When One of a Hundred AI Agents Goes Quiet, Someone Should Know Before the Customer Does

Ellis watches the AI agents that run the Colaberry platform, and tells a person, with evidence, what is healthy, what is broken, and what it cannot see.

WHO NEEDS THIS

The people accountable for a platform run by 100+ scheduled AI agents: the AI engineering manager who owns their reliability, and the governance lead who decides what any agent is allowed to do.

WHY IT MATTERS

Uptime checks say the process is up, not whether each agent did its work. In this platform, a security director read "normal" because its scanner never ran, and a wrapper shared by 104 agents logged failed runs as "no issues".

WHAT IT DOES

1 **Answers reliability questions from the platform's own records, and shows its work.**

39 capabilities, from "did this job run?" to "who can reach this agent?". Every answer cites the rows it rests on, so anyone can check it.

Verified by the platform: 40 of 48 capability stories

2 **Says "unknown" when it cannot see, so silence never reads as health.**

A scanner that never ran, a job with no records, a threshold nobody measured: each is reported as unknown, with the reason, never as fine.

Enforced by 913 tests; each key rule shown to fail when broken

3 **Never changes the live platform on its own.**

It reads, recommends, and rehearses changes on sandbox copies. Merging, deploying, stopping an agent or raising its own authority stay with named people.

Design guarantee: no command can write to the platform

40 / 48	**25**	**16**	**0**
capabilities verified by the platform	live platform risks found; 11 already fixed upstream	higher-autonomy steps rehearsed end to end on sandbox copies	writes to production

WHAT'S NEXT

Shadow mode: Ellis's verdicts compared with approved outcomes on live data, and judged only against the misses and false alarms its manager accepts. The scoring is built; it waits on the first live export and those limits.
